

Tableau Project

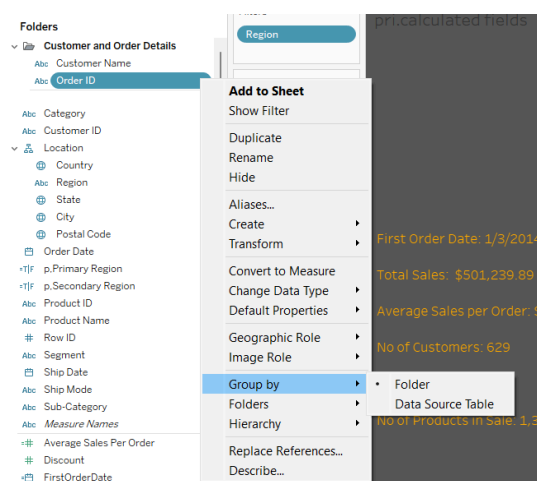

Steps to Perform:

1. Select Sample Superstore as Dataset
 1. Use Sample Superstore Dataset
 2. Select Data
 3. Use Group by from Data Source Table on a Folder to create a folder to segregate the required data for Customer Name and Order ID in order to organize the data thoroughly.

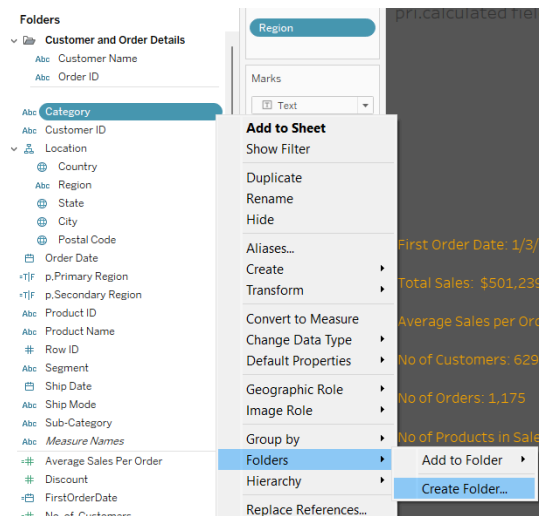

I've uploaded the Sample Superstore Dataset into Tableau and selected the Data from Orders Sheet as below:

Then I've grouped Customer Name and Order ID into a new folder called 'Customer and Order Details'

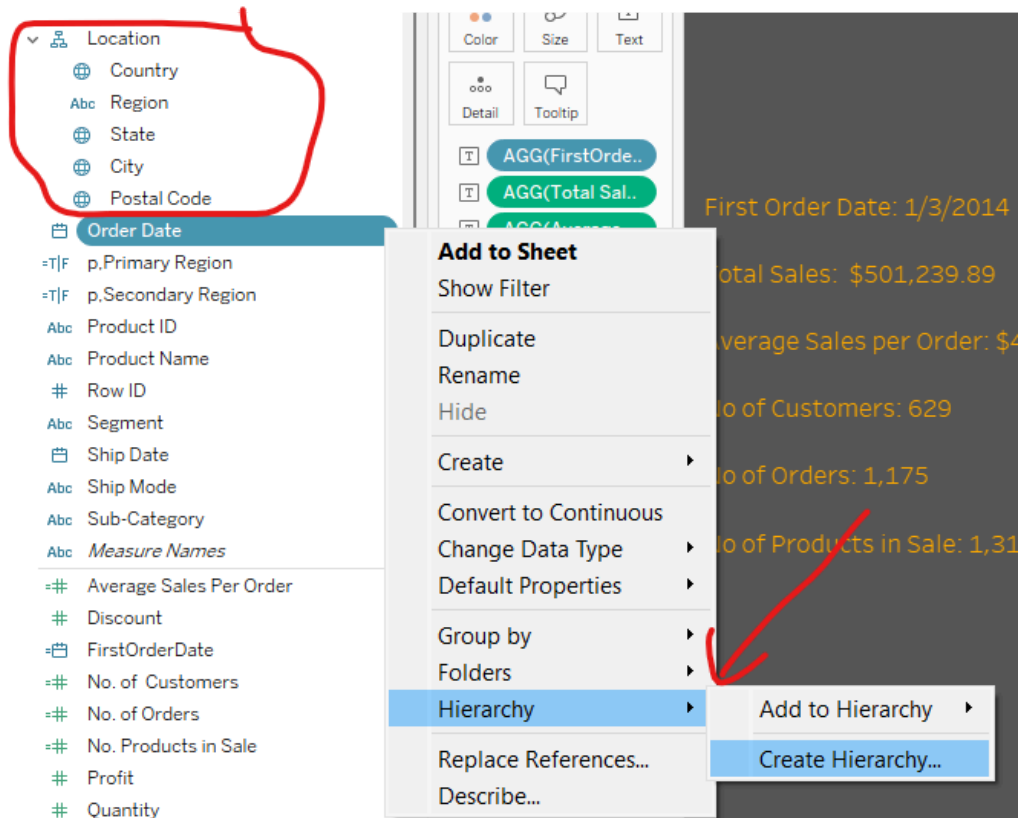

Folder is created as below:

2. Create a hierarchy called Location for the variable Country.

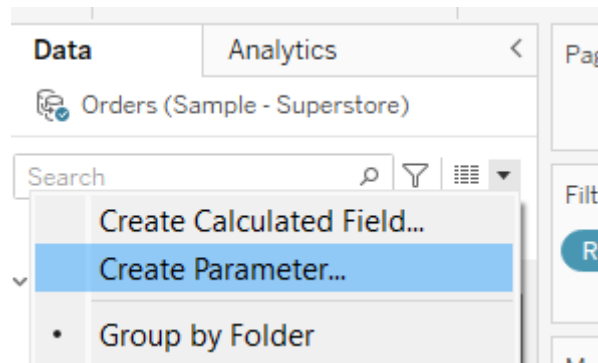

Created a hierarchy named Location with fields as below using *Create Hierarchy*:

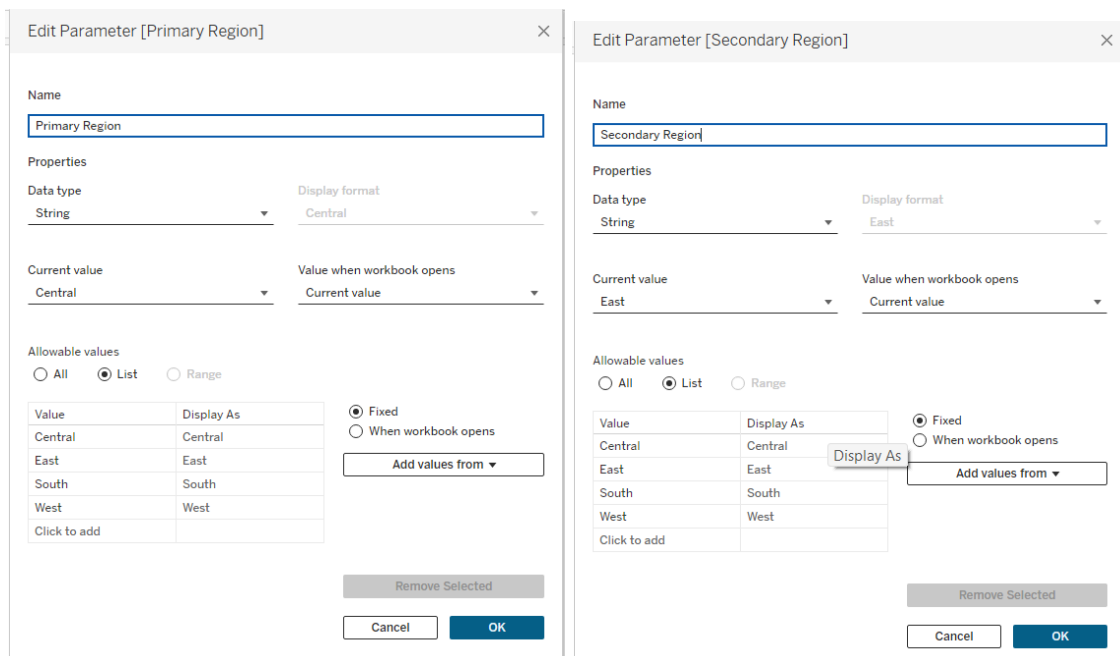

3. Create two parameters: Primary Region and Secondary Region with all regions listed in them. Here, primary and secondary region are the two regions where the sales are being compared.

1. Create Parameters for Primary Region and Secondary Region

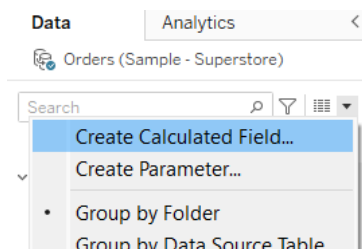

2. Create a Calculated Field for both Primary Region and Secondary Region
Created 2 parameters naming *Primary Region* and *Secondary Region* as below:

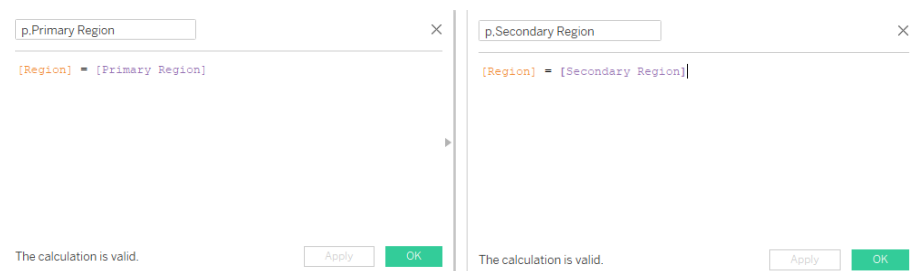

Then,

Also created Calculated Field for both parameters as well,

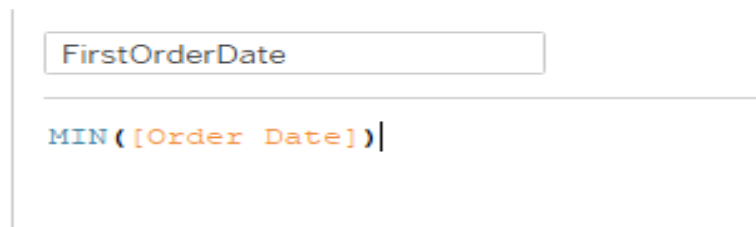

Then,

4. Create a First Order Date

1. Create a Calculated Field and name it as the First Order Date

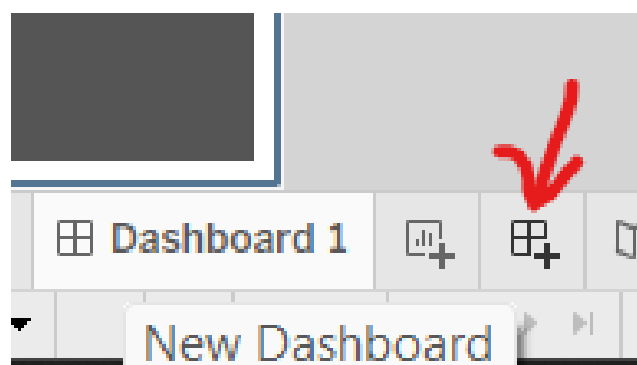

I've created the 'First Order Date' calculated field using the same approach as above and giving the formula as below,

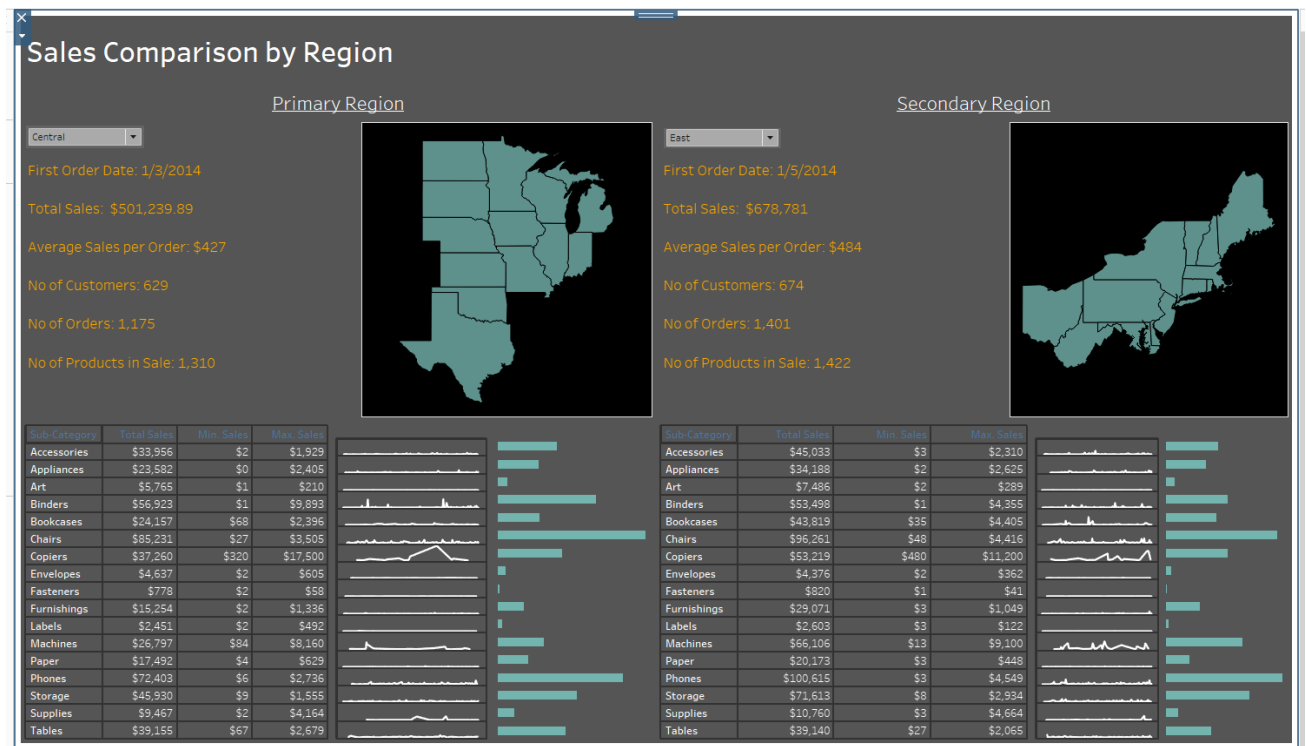

5. Create a dashboard

1. Align all sheets in the dashboard

I've created a new dashboard as below,

I aligned the sheets that I've created accordingly as the reference image to obtain the result as follows:

I've also uploaded the same to the Tableau Public for reference, [Click Here](#) to access that!

6. Partition the dashboard to display the below details of Primary Region and Secondary Region

- First Order Date
- Total Sales
- Average Sales per Order
- No. of Customers
- No. of Orders
- No. of Products in Sale

I've also created the rest of the above-calculated fields and the formulas used are below:

- Total Sales

Total Sales

`SUM([Sales])`

- Average Sales per Order

Average Sales Per Order

`SUM([Sales])/COUNTD([Order ID])`

- No. of Customers

No. of Customers

`COUNTD([Customer ID])`

- No. of Orders

No. of Orders

`COUNTD([Order ID])`

- No. of Products in Sale

No. Products in Sale

`COUNTD([Product ID])`

NOTE: I've used Format for every field and sheet to change the colour/shading of the background / fonts / borders of table as per the reference given
